Security and Risk Management

Individual Project: Executive Summary

1. **Knowledge and Understanding of the Topic/Issues Under Consideration (30%):** You demonstrate sound understanding of supplier, automation, data-integrity and cybersecurity risks. The probability table distinguishes initiating events from material consequences, and the AWS proposal addresses replication, backups and vendor lock-in. However, the connection between the calculations and FAIR needs clearer explanation. The recovery design also needs more detail on failover sequencing and dependencies to support the sub-minute targets. **(Grade: 22%).**
2. **Criticality (30%):** You acknowledge uncertainty, question independence assumptions and distinguish estimated control benefits from guaranteed outcomes. Recommendations address commercial priorities and operational resilience. However, sensitivity analysis and Bayesian updating are proposed rather than demonstrated. The residual probabilities need supporting calculations, and AWS selection requires comparison with alternatives. The claim that correlated events could increase aggregate probability also needs qualification, since dependence can affect event frequency and consequences differently. **(Grade: 20%).**
3. **Use of Relevant Sources (20%):** Relevant academic literature and security standards support the discussion, with useful application to logistics and automated systems. However, the numerical input ranges lack a traceable evidence base or documented elicitation process. AWS performance claims

need direct citations to the relevant technical documentation, and repeated reliance on the core textbook limits the breadth of synthesis. **(Grade: 15%).**

4. **Structure and Presentation (10%):** The submission follows a logical sequence, with clear headings and a useful risk table. Recommendations are ordered and the discussion is generally readable. However, repeated explanations of uncertainty make the executive summary longer than necessary. A recovery architecture diagram would improve clarity, while the reported uncertainty ranges should identify their percentile boundaries. **(Grade: 7%).**
5. **Academic Integrity (10%):** You acknowledge that the estimates are scenario-based and provide citations and a substantial reference list. However, the two NIST publications from 2024 and two ICO entries from 2026 require distinguishing letters and matching citations. Online guidance needs fuller retrieval details. Supporting simulation code or a workbook would also improve the traceability of the reported results. **(Grade: 7%).**

Overall Grade: 71%
